

## 46 Simple Python Exercises

This is version 0.45 of a collection of simple Python exercises constructed (but in many cases only found and collected) by Torbjörn Lager (torbjorn.lager@ling.gu.se). Most of them involve characters, words and phrases, rather than numbers, and are therefore suitable for students interested in language rather than math.

### Very simple exercises

1. Define a function `max()` that takes two numbers as arguments and returns the largest of them. Use the if-then-else construct available in Python. (It is true that Python has the `max()` function built in, but writing it yourself is nevertheless a good exercise.)
2. Define a function `max_of_three()` that takes three numbers as arguments and returns the largest of them.
3. Define a function that computes the *length* of a given list or string. (It is true that Python has the `len()` function built in, but writing it yourself is nevertheless a good exercise.)
4. Write a function that takes a character (i.e. a string of length 1) and returns `True` if it is a vowel, `False` otherwise.
5. Write a function `translate()` that will translate a text into "rövarspråket" (Swedish for "robber's language"). That is, double every consonant and place an occurrence of "o" in between. For example, `translate("this is fun")` should return the string "tothohisos isos fofunon".
6. Define a function `sum()` and a function `multiply()` that sums and multiplies (respectively) all the numbers in a list of numbers. For example, `sum([1, 2, 3, 4])` should return 10, and `multiply([1, 2, 3, 4])` should return 24.
7. Define a function `reverse()` that computes the reversal of a string. For example, `reverse("I am testing")` should return the string "gnitset ma I".
8. Define a function `is_palindrome()` that recognizes palindromes (i.e. words that look the same written backwards). For example, `is_palindrome("radar")` should return `True`.
9. Write a function `is_member()` that takes a value (i.e. a number, string, etc) `x` and a list of values `a`, and returns `True` if `x` is a member of `a`, `False` otherwise. (Note that this is exactly what the `in` operator does, but for the sake of the exercise you should pretend Python did not have this operator.)
10. Define a function `overlapping()` that takes two lists and returns `True` if they have at least one member in common, `False` otherwise. You may use your `is_member()` function, or the `in` operator, but for the sake of the exercise, you should (also) write it using two nested for-loops.
11. Define a function `generate_n_chars()` that takes an integer `n` and a character `c` and returns a string, `n` characters long, consisting only of `c`'s. For example, `generate_n_chars(5, "x")` should return the string "xxxxx". (Python is unusual in that you can actually write an expression `5 * "x"` that will evaluate to "xxxxx". For the sake of the exercise you should ignore that the problem can be solved in this manner.)
12. Define a *procedure* `histogram()` that takes a list of integers and prints a histogram to the screen. For example, `histogram([4, 9, 7])` should print the following:

13. \*\*\*\*

14. \*\*\*\*

\*\*\*\*\*

15. The function `max()` from exercise 1) and the function `max_of_three()` from exercise 2) will only work for two and three numbers, respectively. But suppose we have a much larger number of numbers, or suppose we cannot tell in advance how many they are? Write a function `max_in_list()` that takes a *list* of numbers and returns the largest one.
16. Write a program that maps a list of words into a list of integers representing the lengths of the corresponding words.
17. Write a function `find_longest_word()` that takes a list of words and returns the length of the longest one.
18. Write a function `filter_long_words()` that takes a list of words and an integer `n` and returns the list of words that are longer than `n`.
19. Write a version of a palindrome recognizer that also accepts phrase palindromes such as "Go hang a salami I'm a lasagna hog.", "Was it a rat I saw?", "Step on no pets", "Sit on a potato pan, Otis", "Lisa Bonet ate no basil", "Satan, oscillate my metallic sonatas", "I roamed under it as a tired nude Maori", "Rise to vote sir", or the exclamation "Dammit, I'm mad!". Note that punctuation, capitalization, and spacing are usually ignored.
20. A *pangram* is a sentence that contains all the letters of the English alphabet at least once, for example: *The quick brown fox jumps over the lazy dog*. Your task here is to write a function to check a sentence to see if it is a pangram or not.
21. "99 Bottles of Beer" is a traditional song in the United States and Canada. It is popular to sing on long trips, as it has a very repetitive format which is easy to memorize, and can take a long time to sing. The song's simple lyrics are as follows:

99 bottles of beer on the wall, 99 bottles of beer.  
Take one down, pass it around, 98 bottles of beer on the wall.

The same verse is repeated, each time with one fewer bottle. The song is completed when the singer or singers reach zero.

Your task here is write a Python program capable of generating all the verses of the song.

22. Represent a small bilingual lexicon as a Python dictionary in the following fashion `{"merry": "god", "christmas": "jul", "and": "och", "happy": "gott", "new": "nytt", "year": "år"}` and use it to translate your Christmas cards from English into Swedish. That is, write a function `translate()` that takes a list of English words and returns a list of Swedish words.
23. Write a function `char_freq()` that takes a string and builds a frequency listing of the characters contained in it. Represent the frequency listing as a Python dictionary. Try it with something like `char_freq("abbabcbdbabdbbabababcbcbab")`.
24. In cryptography, a *Caesar cipher* is a very simple encryption techniques in which each letter in the plain text is replaced by a letter some fixed number of positions down the alphabet. For example, with a shift of 3, A would be replaced by D, B would become E, and so on. The method is named after Julius Caesar, who used it to communicate with his generals. *ROT-13* ("rotate by 13 places") is a widely used example of a Caesar cipher where the shift is 13. In Python, the key for ROT-13 may be represented by means of the following dictionary:
25. `key = {'a': 'n', 'b': 'o', 'c': 'p', 'd': 'q', 'e': 'r', 'f': 's', 'g': 't', 'h': 'u',`

```

26.      'i':'v', 'j':'w', 'k':'x', 'l':'y', 'm':'z', 'n':'a', 'o':'b',
      'p':'c',
27.      'q':'d', 'r':'e', 's':'f', 't':'g', 'u':'h', 'v':'i', 'w':'j',
      'x':'k',
28.      'y':'l', 'z':'m', 'A':'N', 'B':'O', 'C':'P', 'D':'Q', 'E':'R',
      'F':'S',
29.      'G':'T', 'H':'U', 'I':'V', 'J':'W', 'K':'X', 'L':'Y', 'M':'Z',
      'N':'A',
30.      'O':'B', 'P':'C', 'Q':'D', 'R':'E', 'S':'F', 'T':'G', 'U':'H',
      'V':'I',
31.      'W':'J', 'X':'K', 'Y':'L', 'Z':'M'}

```

Your task in this exercise is to implement an encoder/decoder of ROT-13. Once you're done, you will be able to read the following secret message:

Pnrfne pvcure? V zhpu cersre Pnrfne fnynq!

Note that since English has 26 characters, your ROT-13 program will be able to both encode and decode texts written in English.

32. Define a simple "spelling correction" function `correct()` that takes a string and sees to it that 1) two or more occurrences of the space character is compressed into one, and 2) inserts an extra space after a period if the period is directly followed by a letter. E.g. `correct("This is very funny and cool.Indeed!")` should return `"This is very funny and cool. Indeed!"` Tip: Use regular expressions!
33. The *third person singular* verb form in English is distinguished by the suffix *-s*, which is added to the stem of the infinitive form: *run* -> *runs*. A simple set of rules can be given as follows:
- If the verb ends in *y*, remove it and add *ies*
  - If the verb ends in *o*, *ch*, *s*, *sh*, *x* or *z*, add *es*
  - By default just add *s*

Your task in this exercise is to define a function `make_3sg_form()` which given a verb in infinitive form returns its third person singular form. Test your function with words like *try*, *brush*, *run* and *fix*. Note however that the rules must be regarded as heuristic, in the sense that you must not expect them to work for all cases. Tip: Check out the string method `endswith()`.

34. In English, the *present participle* is formed by adding the suffix *-ing* to the infinitive form: *go* -> *going*. A simple set of heuristic rules can be given as follows:
- If the verb ends in *e*, drop the *e* and add *ing* (if not exception: *be*, *see*, *flee*, *knee*, etc.)
  - If the verb ends in *ie*, change *ie* to *y* and add *ing*
  - For words consisting of consonant-vowel-consonant, double the final letter before adding *ing*
  - By default just add *ing*

Your task in this exercise is to define a function `make_ing_form()` which given a verb in infinitive form returns its present participle form. Test your function with words such as *lie*, *see*, *move* and *hug*. However, you must not expect such simple rules to work for all cases.

## Higher order functions and list comprehensions

35. Using the higher order function `reduce()`, write a function `max_in_list()` that takes a *list* of numbers and returns the largest one. Then ask yourself: why define and call a new function, when I can just as well call the `reduce()` function directly?
36. Write a program that maps a list of words into a list of integers representing the lengths of the corresponding words. Write it in three different ways: 1) using a for-loop, 2) using the higher order function `map()`, and 3) using *list comprehensions*.
37. Write a function `find_longest_word()` that takes a list of words and returns the length of the longest one. Use only higher order functions.
38. Using the higher order function `filter()`, define a function `filter_long_words()` that takes a list of words and an integer `n` and returns the list of words that are longer than `n`.
39. Represent a small bilingual lexicon as a Python dictionary in the following fashion `{"merry": "god", "christmas": "jul", "and": "och", "happy": "gott", "new": "nytt", "year": "år"}` and use it to translate your Christmas cards from English into Swedish. Use the higher order function `map()` to write a function `translate()` that takes a list of English words and returns a list of Swedish words.
40. Implement the higher order functions `map()`, `filter()` and `reduce()`. (They are built-in but writing them yourself may be a good exercise.)

## Simple exercises including I/O

41. Write a version of a palindrome recogniser that accepts a file name from the user, reads each line, and prints the line to the screen if it is a palindrome.
42. According to Wikipedia, a *semordnilap* is a word or phrase that spells a *different* word or phrase backwards. ("Semordnilap" is itself "palindromes" spelled backwards.) Write a semordnilap recogniser that accepts a file name (pointing to a list of words) from the user and finds and prints all pairs of words that are semordnilaps to the screen. For example, if "stressed" and "desserts" is part of the word list, the the output should include the pair "stressed desserts". Note, by the way, that each pair by itself forms a palindrome!
43. Write a *procedure* `char_freq_table()` that, when run in a terminal, accepts a file name from the user, builds a frequency listing of the characters contained in the file, and prints a sorted and nicely formatted character frequency table to the screen.
44. The *International Civil Aviation Organization (ICAO) alphabet* assigns code words to the letters of the English alphabet acrophonically (Alfa for A, Bravo for B, etc.) so that critical combinations of letters (and numbers) can be pronounced and understood by those who transmit and receive voice messages by radio or telephone regardless of their native language, especially when the safety of navigation or persons is essential. Here is a Python dictionary covering one version of the ICAO alphabet:
45. `d = {'a': 'alfa', 'b': 'bravo', 'c': 'charlie', 'd': 'delta', 'e': 'echo', 'f': 'foxtrot',`
46. `'g': 'golf', 'h': 'hotel', 'i': 'india', 'j': 'juliett', 'k': 'kilo', 'l': 'lima',`
47. `'m': 'mike', 'n': 'november', 'o': 'oscar', 'p': 'papa', 'q': 'quebec', 'r': 'romeo',`
48. `'s': 'sierra', 't': 'tango', 'u': 'uniform', 'v': 'victor', 'w': 'whiskey',`
49. `'x': 'x-ray', 'y': 'yankee', 'z': 'zulu'}`

Your task in this exercise is to write a procedure `speak_ICAO()` able to translate any text (i.e. any string) into *spoken* ICAO words. You need to import at least two libraries: `os` and `time`. On a mac, you have access to the system TTS (Text-To-Speech) as follows: `os.system('say ' + msg)`, where `msg` is the string to be spoken. (Under UNIX/Linux and Windows, something similar might exist.) Apart from the text to be spoken, your procedure also needs to accept two additional parameters: a float indicating the length of the pause between each spoken ICAO word, and a float indicating the length of the pause between each word spoken.

50. A *hapax legomenon* (often abbreviated to *hapax*) is a word which occurs only once in either the written record of a language, the works of an author, or in a single text. Define a function that given the file name of a text will return all its hapaxes. Make sure your program ignores capitalization.

51. Write a program that given a text file will create a new text file in which all the lines from the original file are *numbered* from 1 to *n* (where *n* is the number of lines in the file).

52. Write a program that will calculate the average word length of a text stored in a file (i.e. the sum of all the lengths of the word tokens in the text, divided by the number of word tokens).

53. Write a program able to play the "Guess the number"-game, where the number to be guessed is randomly chosen between 1 and 20. (Source: <http://inventwithpython.com>) This is how it should work when run in a terminal:

```
54. >>> import guess_number
55. Hello! What is your name?
56. Torbjörn
57. Well, Torbjörn, I am thinking of a number between 1 and 20.
58. Take a guess.
59. 10
60. Your guess is too low.
61. Take a guess.
62. 15
63. Your guess is too low.
64. Take a guess.
65. 18
    Good job, Torbjörn! You guessed my number in 3 guesses!
```

66. An *anagram* is a type of word play, the result of rearranging the letters of a word or phrase to produce a new word or phrase, using all the original letters exactly once; e.g., *orchestra* = *carthorse*, *A decimal point* = *I'm a dot in place*. Write a Python program that, when started 1) randomly picks a word *w* from given list of words, 2) randomly permutes *w* (thus creating an anagram of *w*), 3) presents the anagram to the user, and 4) enters an interactive loop in which the user is invited to guess the original word. It may be a good idea to work with (say) colour words only. The interaction with the program may look like so:

```
67. >>> import anagram
68. Colour word anagram: onwbr
69. Guess the colour word!
70. black
71. Guess the colour word!
72. brown
    Correct!
```

73. In a game of *Lingo*, there is a hidden word, five characters long. The object of the game is to find this word by guessing, and in return receive two kinds of clues: 1) the characters that are fully correct, with respect to identity as well as to position, and 2) the characters that are indeed present in the word, but which are placed in the wrong position. Write a program with which one can play Lingo. Use square brackets to mark characters correct in the sense of 1), and ordinary parentheses to mark characters correct in the sense of 2). Assuming, for example, that the program conceals the word "tiger", you should be able to interact with it in the following way:

```
74. >>> import lingo
75. snake
76. Clue: snak(e)
77. fiest
78. Clue: f[i] (e) s(t)
79. times
80. Clue: [t][i]m[e]s
81. tiger
    Clue: [t][i][g][e][r]
```

## Somewhat harder exercises

82. A *sentence splitter* is a program capable of splitting a text into sentences. The standard set of heuristics for sentence splitting includes (but isn't limited to) the following rules:

Sentence boundaries occur at one of "." (periods), "?" or "!", except that

. Periods followed by whitespace followed by a lower case letter are not sentence boundaries.

- Periods followed by a digit with no intervening whitespace are not sentence boundaries.
- Periods followed by whitespace and then an upper case letter, but preceded by any of a short list of titles are not sentence boundaries. Sample titles include *Mr.*, *Mrs.*, *Dr.*, and so on.
- Periods internal to a sequence of letters with no adjacent whitespace are not sentence boundaries (for example, *www.aptex.com*, or *e.g.*).
- Periods followed by certain kinds of punctuation (notably comma and more periods) are probably not sentence boundaries.

Your task here is to write a program that given the name of a text file is able to write its content with each sentence on a separate line. Test your program with the following short text: *Mr. Smith bought cheapsite.com for 1.5 million dollars, i.e. he paid a lot for it. Did he mind? Adam Jones Jr. thinks he didn't. In any case, this isn't true... Well, with a probability of .9 it isn't.* The result should be:

```
Mr. Smith bought cheapsite.com for 1.5 million dollars, i.e. he paid a
lot for it.
Did he mind?
Adam Jones Jr. thinks he didn't.
In any case, this isn't true...
Well, with a probability of .9 it isn't.
```

83. An *anagram* is a type of word play, the result of rearranging the letters of a word or phrase to produce a new word or phrase, using all the original letters exactly once; e.g., *orchestra* = *carthorse*. Using the word list at <http://www.puzzlers.org/pub/wordlists/unixdict.txt>, write a program that finds the sets of words that share the same characters that contain the most words in them.

84. Your task in this exercise is as follows:

- . Generate a string with N opening brackets ("[" ) and N closing brackets ("]"), in some arbitrary order.
- a. Determine whether the generated string is *balanced*; that is, whether it consists entirely of pairs of opening/closing brackets (in that order), none of which mis-nest.

Examples:

[]	OK	] [	NOT OK
[] []	OK	] [] [	NOT OK
[ [] [] ]	OK	[ [] ] [ [] ]	NOT OK

85. A certain childrens game involves starting with a word in a particular category. Each participant in turn says a word, but that word must begin with the final letter of the previous word. Once a word has been given, it cannot be repeated. If an opponent cannot give a word in the category, they fall out of the game. For example, with "animals" as the category,

- 86. Child 1: dog
- 87. Child 2: goldfish
- 88. Child 1: hippopotamus
- 89. Child 2: snake
- 90. ...

Your task in this exercise is as follows: Take the following selection of 70 English Pokemon names (extracted from [Wikipedia's list of Pokemon](#)) and generate the/a sequence with the highest possible number of Pokemon names where the subsequent name starts with the final letter of the preceding name. No Pokemon name is to be repeated.

audino bagon baltoy banette bidoof braviary bronzor carracosta

 seaking  
 sealeo silcoon simisear snivy snorlax spoink starly tirtouga trapinch  
 treecko  
 tyrogue vigoroth vulpix wailord wartortle whiskur wingull yamask

91. An *alternade* is a word in which its letters, taken alternatively in a strict sequence, and used in the same order as the original word, make up at least two other words. All letters must be used, but the smaller words are not necessarily of the same length. For

example, a word with seven letters where every second letter is used will produce a four-letter word and a three-letter word. Here are two examples:

- 92.     "board": makes "bad" and "or".
- 93.     "waists": makes "wit" and "ass".

Using the word list at <http://www.puzzlers.org/pub/wordlists/unixdict.txt>, write a program that goes through each word in the list and tries to make two smaller words using every second letter. The smaller words must also be members of the list. Print the words to the screen in the above fashion.
